

## Training data

Every machine learning algorithm needs sets of data, which is called training dataset. Training data sets and input data together we believe that construct predictive relationship between input data and output action. Training data should be as closer to the actual output as possible. A well pre-labeled and impartial data will help trained classifier to perform more accurate prediction. Amount of training data set depends on complexity of the concept of predictive model.

Our algorithm required training data sets of alphabets as we are predicting alphabets. Concept device designed to predict all alphabets only, so our training dataset would cover all alphabets with enough frequency. We designed training text dataset from pangram sentences which covers all alphabets in meaningful sentences.

*“The five boxing wizards jump quickly”*

*“Sixty zippers were quickly picked from the woven jute bag”*

*“Sphinx of black quartz: judge my vow.”*

## Layer Min\_Max Matrix

As discussed in setup procedure, we divided computer keyboard alphabets in three layers : Upper layer (keys: ‘q’, ‘w’, ‘e’, ‘r’, ‘t’, ‘y’, ‘u’, ‘i’, ‘o’, ‘p’), middle layer (keys: ‘a’, ‘s’, ‘d’, ‘f’, ‘g’, ‘h’, ‘j’, ‘k’, ‘l’) and lower layer (keys: ‘z’, ‘x’, ‘c’, ‘v’, ‘b’, ‘n’, ‘m’). This 3 X 16 matrix contain data of flex sensor input for each layer row wise. Left part of half matrix (3X8) contains minimum value of flex sensors while typing in particular layer by fingers. Remaining half part contains maximum value of flex sensors for the same process. By default we set all values to 2000 because our flex sensor only goes from 100 – 1200, that means after training if we find any two values 2000, we can conclude non used finger in particular layer.

## Finger Vs Alphabets occurrence matrix

Our algorithm selects most probable alphabet for that finger in that layer. To achieve this goal, matrix is constructed by monitoring occurrence of alphabets by finger and updating it in format like alphabets in row and finger in columns. This matrix updates in both phase training phase and when device is in actual use. It is 27X10 sized matrix with labeled finger name in first row and alphabets in first column. Second column filled with layer information in form of '0','1' or '2'. '0' represent Upper Layer(UL) , '1' represent Middle Layer(ML) and '2' represent Lower Layer(LL)

## **Transition Matrix**

To make prediction more powerful, we use probability of transition of alphabets in words. It is 26X26 sized matrix with considering labels alphabets from a-z in row and column both. This matrix contains occurrences of alphabet to the following alphabet. Purpose of building this matrix is to predict next probable alphabets based on current alphabet input and also remove unwanted zero probability alphabets.

This matrix is already constructed based on words from a dictionary, which will be used to predict the words. This matrix also gets updated when device is in actual use to get more accurate prediction. (Refer Image on Page#18)

## **Dictionary**

One dictionary is maintained to predict final word based on input alphabets. This is pool of words collected from open source Shakespeare's work. Concept device only predict words from dictionary only.
